 Positroid strata are subvarieties inside Grassmannians [Pos06, KLS13], and they are interesting objects to study from both representation theory [Paw23, Pre23] and mathematical physics [AHBC⁺16] perspectives.

- Positroid strata are subvarieties inside Grassmannians [Pos06, KLS13], and they are interesting objects to study from both representation theory [Paw23, Pre23] and mathematical physics [AHBC⁺16] perspectives.
- A special feature on positroid strata is their cluster structures [GL19, SSBW19], which are typically captured combinatorially by reduced plabic graphs.

- Positroid strata are subvarieties inside Grassmannians [Pos06, KLS13], and they are interesting objects to study from both representation theory [Paw23, Pre23] and mathematical physics [AHBC⁺16] perspectives.
- A special feature on positroid strata is their cluster structures [GL19, SSBW19], which are typically captured combinatorially by reduced plabic graphs.

 However, one can only realize certain mutations as moves on reduced plabic graphs.

- Positroid strata are subvarieties inside Grassmannians [Pos06, KLS13], and they are interesting objects to study from both representation theory [Paw23, Pre23] and mathematical physics [AHBC⁺16] perspectives.
- A special feature on positroid strata is their cluster structures [GL19, SSBW19], which are typically captured combinatorially by reduced plabic graphs.

- However, one can only realize certain mutations as moves on reduced plabic graphs.
- On the other hand, the recent introduction and development of Legendrian weaves [CZ22, CW22, CGG⁺22] has built an explicit connection between cluster structures and geometry.

- Positroid strata are subvarieties inside Grassmannians [Pos06, KLS13], and they are interesting objects to study from both representation theory [Paw23, Pre23] and mathematical physics [AHBC⁺16] perspectives.
- A special feature on positroid strata is their cluster structures [GL19, SSBW19], which are typically captured combinatorially by reduced plabic graphs.

- However, one can only realize certain mutations as moves on reduced plabic graphs.
- On the other hand, the recent introduction and development of Legendrian weaves [CZ22, CW22, CGG⁺22] has built an explicit connection between cluster structures and geometry.
- The initial goal of our project is to construct weaves from reduced plabic graphs, which gives rise to a geometric interpretation of the cluster structures on positroid strata. As an application, we prove the conjecture of the equality between the Muller-Speyer twist map and the Donaldson-Thomas transformation.

Positroid Strata and Reduced Plabic Graphs

$$\operatorname{Gr}_{m,n}(\mathbb{R}) = \operatorname{GL}_m(\mathbb{R}) \setminus \operatorname{Mat}_{m,n}^{\operatorname{full ranked}}(\mathbb{R})$$

$$\operatorname{Gr}_{3,6}(\mathbb{R}) = \operatorname{GL}_3(\mathbb{R}) \setminus \begin{pmatrix} x_{11} & x_{12} & x_{13} & x_{14} & x_{15} & x_{16} \\ x_{21} & x_{22} & x_{23} & x_{24} & x_{25} & x_{26} \\ x_{31} & x_{32} & x_{33} & x_{34} & x_{35} & x_{36} \end{pmatrix}$$

$$\operatorname{Gr}_{3,6}(\mathbb{R}) = \operatorname{GL}_3(\mathbb{R}) \setminus \begin{pmatrix} x_{11} & x_{12} & x_{13} & x_{14} & x_{15} & x_{16} \\ x_{21} & x_{22} & x_{23} & x_{24} & x_{25} & x_{26} \\ x_{31} & x_{32} & x_{33} & x_{34} & x_{35} & x_{36} \end{pmatrix}$$

◆□▶ < @ ▶ < E ▶ < E ▶ E の Q @ 6/29</p>

Definition of Positroids

Positroid strata come from a stratification of $\operatorname{Gr}_{m,n}^{\geq 0}(\mathbb{R})$ [Pos06]. For $m \leq n$,

$$\operatorname{Gr}_{3,6}(\mathbb{R}) = \operatorname{GL}_3(\mathbb{R}) \setminus \begin{pmatrix} x_{11} & x_{12} & x_{13} & x_{14} & x_{15} & x_{16} \\ x_{21} & x_{22} & x_{23} & x_{24} & x_{25} & x_{26} \\ x_{31} & x_{32} & x_{33} & x_{34} & x_{35} & x_{36} \end{pmatrix}$$

For any *m*-element subset *I* of $[n] := \{1, 2, ..., n\}$, the **Plücker coordinate** Δ_I is the determinant of the submatrix formed by the column vectors indexed by *I*. For example,

$$\Delta_{2,3,5} = \det \begin{pmatrix} x_{12} & x_{13} & x_{15} \\ x_{22} & x_{23} & x_{25} \\ x_{32} & x_{33} & x_{35} \end{pmatrix}.$$

$$C_{\mathcal{P}} := \{ [M] \in \mathrm{Gr}_{m,n}^{\geq 0}(\mathbb{R}) \mid \Delta_{I}(M) \neq 0 \iff I \in \mathcal{P} \}.$$

Definition

 \mathcal{P} is called a **positroid** of type (m, n) if the subset $C_{\mathcal{P}} \subset \operatorname{Gr}_{m,n}^{\geq 0}(\mathbb{R})$ is non-empty. We call m the **rank** of \mathcal{P} .

For each $i \in [n] := \{1, 2, \dots, n\}$, we define a linear order $<_i$ on [n] by

 $i <_i i + 1 <_i \cdots <_i n <_i 1 <_i \cdots <_i i - 1.$

◆□▶ < @ ▶ < E ▶ < E ▶ E の Q @ 7/29</p>

This linear order induces a lexicographic partial order on $\binom{[n]}{m}$.

For each $i \in [n] := \{1, 2, ..., n\}$, we define a linear order $<_i$ on [n] by $i <_i i + 1 <_i \dots <_i n <_i 1 <_i \dots <_i i - 1$.

This linear order induces a lexicographic partial order on $\binom{[n]}{m}$. For example, to compare $\{1,4,5\}$ and $\{3,5,6\}$ in $\binom{[6]}{3}$ with respect to $<_2$, we have

$$\{1, 4, 5\}$$

 $\{3, 5, 6\}$

Definition ([KLS13])

Let $\mathcal{P} \subset {\binom{[n]}{m}}$ be a positroid and let $\mathcal{I}_{\mathcal{P}} = (I_1, \ldots, I_n)$ be its Grassmann necklace. The **(open) positroid stratum** $\Pi_{\mathcal{P}}^{\circ}$ is defined to be the following subvariety of $\widetilde{\operatorname{Gr}}_{m,n}$:¹

$$\Pi_{\mathcal{P}}^{\circ} = \left\{ [M] \in \widetilde{\operatorname{Gr}}_{m,n} \; \middle| \; \prod_{i} \Delta_{I_{i}}(M) \neq 0 \text{ and } \Delta_{I}([M]) = 0 \text{ for all } I \notin \mathcal{P} \right\}$$

 $^{^1}$ Here $\widehat{\mathrm{Gr}}_{m,n}$ denotes the affine cone of the Grassmannian $\mathrm{Gr}_{m,n}$ with respect to the Plücker embedding. $^{\circ}$ 9.0 $^{\circ}$ 7/29

Positroid Legendrian Link

Given a Grassmann necklace $\mathcal{I}_{\mathcal{P}} = (I_1, I_2, \dots, I_n)$, we can draw a Legendrian link² $\Lambda_{\mathcal{P}}$ by

²A Legendrian link is a link in $\mathbb{R}^3_{x,y,z}$ satisfying y = dz/dx. Here we are describing the Legendrian link as a satellite of the max tb unknot.

Given a Grassmann necklace $\mathcal{I}_{\mathcal{P}} = (I_1, I_2, \dots, I_n)$, we can draw a Legendrian link² $\Lambda_{\mathcal{P}}$ by

- List elements in I_i with respect to the $<_i$ ordering.
- Connect the corresponding elements in I_i and I_{i+1} (index mod n).
- Connect the remaining pair of distinct elements in I_i and I_{i+1} (index mod n).

 2 A Legendrian link is a link in $\mathbb{R}^3_{x,y,z}$ satisfying y = dz/dx. Here we are describing the Legendrian link as a satellite of the max tb unknot.

Bounded Affine Permutations

In a Grassmann necklace $\mathcal{I}_{\mathcal{P}} = (I_1, \ldots, I_n)$, any two cyclically consecutive entries differ at most by one element. Thus, we define the **bounded affine permutation** f of \mathcal{P} by

$$f_{\mathcal{P}}(i) = \begin{cases} j & \text{if } i \in I_i \text{ and } I_{i+1} = (I_i \setminus \{i\}) \cup \{j\} \text{ for } j > i, \\ j+n & \text{if } i \in I_i \text{ and } I_{i+1} = (I_i \setminus \{i\}) \cup \{j\} \text{ for } j \leq i, \\ i & \text{if } i \notin I_i. \end{cases}$$

Theorem (Postnikov [Pos06])

Positroids, Grassmann necklaces, and bounded affine permutations are all in bijection with each other.

In particular, the rank of a positroid can be recovered from its bounded affine permutation as the following average:

$$m=\frac{1}{n}\sum_{i=1}^{n}(f_{\mathcal{P}}(i)-i).$$

In a Grassmann necklace $\mathcal{I}_{\mathcal{P}} = (I_1, \dots, I_n)$, any two cyclically consecutive entries differ at most by one element. Thus, we define the **bounded affine permutation** f of \mathcal{P} by

$$f_{\mathcal{P}}(i) = \begin{cases} j & \text{if } i \in I_i \text{ and } I_{i+1} = (I_i \setminus \{i\}) \cup \{j\} \text{ for } j > i, \\ j+n & \text{if } i \in I_i \text{ and } I_{i+1} = (I_i \setminus \{i\}) \cup \{j\} \text{ for } j \leq i, \\ i & \text{if } i \notin I_i. \end{cases}$$

One can also think of $f_{\mathcal{P}}$ as searching for the first column vector $v_{f_{\mathcal{P}}(i)}$ to the right of v_i (cyclically) in [*M*] such that v_i is in the span of $\{v_{i+1}, \ldots, v_{f_{\mathcal{P}}(i)}\}$.

Theorem (Postnikov [Pos06])

Positroids, Grassmann necklaces, and bounded affine permutations are all in bijection with each other.

In particular, the rank of a positroid can be recovered from its bounded affine permutation as the following average:

$$m=\frac{1}{n}\sum_{i=1}^{n}(f_{\mathcal{P}}(i)-i).$$

For example, the top dimensional positroid stratum in $\operatorname{Gr}_{m,n}$ corresponds to the bounded affine permutation $f_{\mathcal{P}}(i) = i + m$.

Each positroid stratum $\Pi_{\mathcal{P}}^{\circ}$ is a cluster $\mathcal{A}\text{-variety.}$ An initial cluster seed of $\Pi_{\mathcal{P}}^{\circ}$ can be constructed from a reduced plabic graph.

Reduced Plabic Graphs

Each positroid stratum $\Pi^{\circ}_{\mathcal{P}}$ is a cluster \mathcal{A} -variety. An initial cluster seed of $\Pi^{\circ}_{\mathcal{P}}$ can be constructed from a **reduced plabic graph**.

A plabic graph \mathbb{G} is a planar graph on a disk \mathbb{D} with solid and empty vertices and external edges attached to $\partial \mathbb{D}$. We label the external edges by $1, 2, \ldots, n$.

A plabic graph is said to be **reduced** if its zig-zags do not form loops, self-intersection, or parallel bigons.

A reduced plabic graph \mathbb{G} is associated with a positroid \mathcal{P} if the zig-zags in \mathbb{G} go from *i* to $f_{\mathcal{P}}(i) \mod n$ for each *i*.

Let \mathbb{G} be a reduced plabic graph for a positroid \mathcal{P} of type (m, n). To each face F of \mathbb{G} , we can associate an *m*-element set I_F by using the targets of zig-zags (also known as the **target labeling**).

We can then draw a collection of arrows across edges such that they form a counterclockwise cycle around solid vertices. This defines a quiver Q with frozen vertices. The pair $(\{\Delta_{I_F}\}_F, Q)$ defines an initial seed for the cluster structure on $\Pi_{\mathcal{D}}^{\circ}$.

Theorem (Casals-Le-Sherman-Bennett-W.)

Suppose \mathbb{G} is a reduced plabic graph associated with a positroid \mathcal{P} of rank m. Let $\mathbb{G}_m := \mathbb{G}$ and define $\mathbb{G}_k := \mathbb{G}_{k+1}^{\downarrow}$. Then $\mathfrak{w} := \bigcup_{k=1}^{m-1}$ is a Legendrian m-weave, and it encodes the same cluster structure on $\Pi_{\mathcal{P}}^{\circ}$ as \mathbb{G} . We call this weave \mathfrak{w} the **positroid** weave associated with \mathbb{G} .

Theorem (Casals-Le-Sherman-Bennett-W.)

Note that we can recover the target labeling of the faces of $\mathbb G$ by repeating this backward iteration once more.

Mutation at Non-Square Faces

As we have mentioned at the beginning, one cannot realize mutation at non-square faces using reduced plabic graphs. However, this can be done using Legendrian weaves.

Theorem

The boundary of a positroid weave \mathfrak{w} is $\Lambda_{\mathcal{P}}$ (in other words, $\mathcal{L}_{\mathfrak{w}}$ is an exact Lagrangian filling of $\Lambda_{\mathcal{P}}$). Moreover, $\Pi_{\mathcal{P}}^{\circ} \cong \mathfrak{M}(\Lambda_{\mathcal{P}}; \mathfrak{t})$, where $\Lambda_{\mathcal{P}}$ is the positroid Legendrian link associated with \mathcal{P} and \mathfrak{t} is a certain way to decorate $\Lambda_{\mathcal{P}}$ with base points.

Theorem

Moreover, $\Pi_{\mathcal{P}}^{\circ} \cong \mathfrak{M}(\Lambda_{\mathcal{P}}; \mathfrak{t})$, where $\Lambda_{\mathcal{P}}$ is the positroid Legendrian link associated with \mathcal{P} and \mathfrak{t} is a certain way to decorate $\Lambda_{\mathcal{P}}$ with base points.

In [CGG⁺22], Casals, Gorsky, Gorsky, Le, Shen, and Simental use a special family of weaves called **Demazure weaves** to describe cluster structures on braid varieties.

Theorem

For each $1 \le i \le n$, there is a weave equivalence that turns the positroid weave \mathfrak{w} to a Demazure weave. In particular, these weave equivalences are in bijection with acyclic **perfect orientations** on \mathbb{G} .

Theorem

The boundary of a positroid weave \mathfrak{w} is $\Lambda_{\mathcal{P}}$ (in other words, $\mathcal{L}_{\mathfrak{w}}$ is an exact Lagrangian filling of $\Lambda_{\mathcal{P}}$). Moreover, $\Pi_{\mathcal{P}}^{\circ} \cong \mathfrak{M}(\Lambda_{\mathcal{P}}; \mathfrak{t})$, where $\Lambda_{\mathcal{P}}$ is the positroid Legendrian link associated with \mathcal{P} and \mathfrak{t} is a certain way to decorate $\Lambda_{\mathcal{P}}$ with base points.

Theorem

For each $1 \le i \le n$, there is a weave equivalence that turns the positroid weave \mathfrak{w} to a Demazure weave. In particular, these weave equivalences are in bijection with acyclic **perfect orientations** on \mathbb{G} .

In [GK13], Goncharov and Kenyon construct a **conjugate surface** $S_{\mathbb{G}}$ from a reduced plabic graph \mathbb{G} . Shende, Treumann, Williams, and Zaslow [STWZ19] prove that the conjugate surface $S_{\mathbb{G}}$ can be seen as an exact Lagrangian surface in $T^*\mathbb{D}$.

Theorem

The iterative T-shift procedure can be viewed geometrically as a Hamiltonian isotopy from $S_{\mathbb{G}}$ to $L_{\varpi}.$

In [CW22] and [CGG⁺22], the **Donaldson-Thomas transformation** of the cluster ensemble can be geometrically described as the composition of a Legendrian isotopy that cyclically rotates $\Lambda_{\mathcal{P}}$ and a contactomorphism that is analogous to a transposition. By comparing this action with the Muller-Speyer twist map [MS17] on positroid strata, we prove that the following conjecture.

Theorem

The Muller-Speyer twist map on a positroid stratum coincides with its (quasi-cluster) Donaldson-Thomas transformation.

In [CW22] and [CGG⁺22], the **Donaldson-Thomas transformation** of the cluster ensemble can be geometrically described as the composition of a Legendrian isotopy that cyclically rotates $\Lambda_{\mathcal{P}}$ and a contactomorphism that is analogous to a transposition. By comparing this action with the Muller-Speyer twist map [MS17] on positroid strata, we prove that the following conjecture.

Theorem

The Muller-Speyer twist map on a positroid stratum coincides with its (quasi-cluster) Donaldson-Thomas transformation.

Corollary

The target labeling seeds and source labeling seeds are quasi-cluster equivalent.

Corollary

The target labeling seeds and source labeling seeds are quasi-cluster equivalent.

Recently, Decampo and Muller [DM23] introduce a moduli space of **linear recurrence** with a cluster \mathcal{X} structure for each positroid. These moduli spaces can be thought of as the "mirror" of positroid strata. We can modify our construction and obtain a different decorated flag moduli space with the same cluster \mathcal{X} structure as loc. cit.

Thank You!
